In nearly every case the voltage would be constant for most of the process and then reduce slightly, due to internal resistance of the circuitry, as the generation process nears completion and as the circuit goes into constant current mode. Some colloidal silver generators which do not turn off automatically by electronic sensing, will use a constant current mode at the end of the process using a current limiting system, so that the current cannot exceed a certain amount.

Constant Current Colloidal Silver Generator Explained

SilverGen CONSTANT CURRENT colloidal silver generators are high tech. Constant voltage generators operate as follows. and why they aren't much good. When an electrical source of voltage that is fixed in value such as 27 or 36 volts (the voltage supplied by 3 or 4 - 9 volt batteries in series connection) is used to generate ionic/colloidal silver, the voltage is connected to the silver electrodes which are in the water.

They don't make safe colloidal silver because they aren't constant current. What happens is that you start with 27 volts and silver electrodes in the distilled water. As the ionic silver is formed in the water it causes the resistance of the water to drop. This makes the current increase and this causes larger particles of silver to form.

Current flow can become excessive as the "conductivity" inside of the C.S. generator increases, however, so adding a 28 volt, 40mA rated incandescent bulb "in series" is also recommended at this operating voltage, to limit the maximum possible current flow through the system to ~40mA (milli-Amps, or thousandths of an amp.)
